13. ABSTRACT (Maximum 200 words)  The effect of tensile stress on hydrogen diffusion has been determined for Type 303 stainless steel, A286 CRES, and Waspaloy and IN100 nickel-base alloys. It was found that hydrogen diffusion coefficients are not significantly affected by stress, while the hydrogen permeabilities are greatly affected in Type 303 stainless steel and A286 CRES (iron-based alloys), but are affected little in Waspaloy (nickel-base) and not affected at all in IN100 (nickel base). These observations might be taken as an indication that hydrogen permeabilities are affected by stress in iron-based alloys, but only slightly affected in nickel-based alloys. However, it is too early to make such a generalization based on the study of only these four alloys.

## TECHNICAL MEMORANDUM

### THE EFFECT OF TENSILE STRESS ON HYDROGEN DIFFUSION IN METAL ALLOYS

#### INTRODUCTION

The present work was undertaken to provide further information regarding the effect of tensile stress on the hydrogen distribution in metals on charging and also on the effect on other parameters involved, such as mean hydrogen concentrations and hydrogen diffusion coefficients. Experimentally, it is desirable to carry out the investigations in the elastic region since determination of the hydrogen diffusion coefficient is a sensitive function of the sample radius, and deformation of the sample in the plastic region would prevent accurate determination of this parameter. However, small plastic deformations did occur at 90-percent yield, but these are not considered great enough to seriously affect the results.

Other studies concerning the influence of stress on hydrogen diffusion have been carried out. Wriedt and Oriani<sup>1</sup> showed that an elastically stressed 75-weight-percent palladium to 25-weight-percent silver alloy in a hydrogen atmosphere increased in hydrogen content under uniaxial tension and decreased in hydrogen content under uniaxial compression. Bockris et al.<sup>2</sup> studied Armco iron and 4340 steel and found that hydrogen permeation was increased by tensile stress and decreased by compressive stress, with the hydrogen diffusion coefficient being unaffected by the applied stress.

Results for A286 CRES steel have been reported previously.<sup>3</sup> The present study includes work on Type 303 stainless steel (303SS) and nickel-base alloys IN100 and Waspaloy. There are, therefore, two iron-base alloys and two nickel-base alloys, and it is of interest to compare the effect of stress on the hydrogen diffusion in these different alloys.

This report presents the results obtained by electrochemical methods on all four alloys under stresses corresponding to 0, 25, 50, 75, and 90 percent of yield. Calculations were made using the standard procedure previously developed and described<sup>4</sup> for data extending to large time (0 to 150,000 s).

#### EXPERIMENTAL

The EG&G-PARC model 350A corrosion measurement console was employed for the electrochemical measurements of hydrogen desorption.

Samples consisted of tensile specimens of the metal alloys which were 5.08-cm (2-in) long with a gauge length of 1.905 cm (0.75 in) and a diameter of 0.3175 cm (0.125 in). The specimens were threaded at both ends with 1/4-20 NC threads. All metal parts, except for the gauge section, were coated with Micromask stop-off lacquer to prevent electrical contact.

The specimens were mounted on a Korros Data slow strain rate (SSR) machine, enclosed in a glass cell having a 1-L capacity. The cell was filled with a 0.1N sodium hydroxide (NaOH) solution which provided a medium for charging of the sample with hydrogen and for conduction of the hydrogen

desorption current. The SSR machine was then driven to the proper load level, which was maintained throughout the charging and desorption stages. Sample blanks were run at a constant potential of 0.0 V versus the saturated calomel electrode. The period of measurement was 150,000 s for each sample with values of the current being recorded every 500 s. After running the blanks, the specimens were then electrolytically charged with hydrogen for a period of 1 h at a current density of 90 mA/cm<sup>2</sup>.

Measurements of the desorption current were initiated immediately on completion of charging, with current measurements being taken in the same manner as for the blanks. After completion of each run, data were read to an IBM PC/AT computer for calculation purposes. Currents due only to hydrogen were obtained by subtraction of the currents for blanks. After data for both the hydrogen-containing sample and its blank were obtained, the experimental curve  $Q(t)$ , the coulombs of hydrogen desorbed after time  $t$ , versus time was obtained through integration of the current-time curves. Values of  $Q(t)$  were corrected for cutoff at finite time (150,000 s) by procedures described previously,<sup>4</sup> obtaining values for  $Q^{\infty}_{HM}$ , the observed concentration  $\bar{C}$ , the apparent surface concentration  $C_o$ , and the hydrogen-diffusion coefficient  $D$ . The procedures for obtaining these quantities are described in Reference 4. Theoretical hydrogen-desorption curves were calculated for both uniform and nonuniform hydrogen distributions using the computer program PDEONE.<sup>5</sup>

Residual hydrogen concentrations (hydrogen remaining after complete desorption of the mobile hydrogen) were determined using the Leco Model RH2 hydrogen analyzer. Calibration of the hydrogen analyzer was accomplished using standard samples. The gauge sections of the tensile test specimens were retained for these analyses after removing the remaining shoulders and threaded sections at each end with a diamond saw.

## RESULTS

### Type 303 Stainless Steel

The material used in this investigation had an ultimate tensile strength (UTS) of 589 MPa (85.4 ksi) and a yield strength (YS) of 265 MPa (38.4 ksi). The chemistry of the Type 303SS alloy is presented in Table 1. Hydrogen desorption curves, experimental and theoretical, are shown in Figures 1 through 5. Results were obtained under stresses of 0, 66.2 MPa (9.6 ksi), 132.3 MPa (19.2 ksi), 198.5 MPa (28.8 ksi), and 238.5 MPa (34.6 ksi). These stress levels represent 0, 25, 50, 75, and 90 percent of the yield strength, respectively.

Results from the data analyses are presented in Table 2. These indicate that there is no significant trend in the values of the diffusion coefficients at the various stress levels. Values of  $C_o$ , the apparent concentration of hydrogen at the sample surface,  $\bar{C}$ , the mean mobile hydrogen concentration in the sample, and the percent uniformity of the initial hydrogen concentration on charging (parameters related to hydrogen solubility) indicate that the permeability of Type 303SS increases with stress up to about 50 percent of yield and decreases thereafter. The curve relating the variation of percent uniformity with percent yield is shown in Figure 6, the data points being fitted with a second-degree polynomial.

Hydrogen trapping as a function of stress is shown in Table 3. The percent of trapped or residual hydrogen is quite high in all cases, the average percent residual hydrogen being 62.3 percent. The reason for the very high percentage of trapped hydrogen is not known, but may be due to the high weight percent of sulfur (0.25 percent) present in this alloy. Magnified photographs of the metal matrix show that

there are numerous stringers interspersed throughout, which are probably filled with sulfur or metallic sulfides. The hydrogen may be trapped in these regions either by the sulfur-containing materials or as molecular hydrogen.

### **A286 CRES**

A286 CRES had a chemistry (Table 4) conforming to AMS 5732, but the UTS of 1,210 MPa (175.6 ksi) and a YS of 933 MPa (135.3 ksi) indicated that the material had been solution treated, cold worked, and precipitation heat treated. Hydrogen desorption curves are shown in Figures 7 through 11. Results were obtained under stresses of 0, 233 MPa (33.9 ksi), 467 MPa (67.7 ksi), 700 MPa (101.6 ksi), and 840 MPa (121.9 ksi), representing 0, 25, 50, 75, and 90 percent of the YS.

Results from the data analyses are presented in Table 5. Again, no significant trend in values of the diffusion coefficients is noted. Values of  $C_o$ ,  $\bar{C}$ , and the percent uniformity of the initial hydrogen concentration on charging indicate that the permeability of A286 CRES increases up to about 60 percent of the yield strength, decreasing thereafter. The curve relating the variation of percent uniformity with percent yield is shown in Figure 12. Again, the data points were fitted with a second-degree polynomial.

The hydrogen trapping as a function of stress is shown in Table 5. The average percent of trapped hydrogen is 7.6 percent, much lower than that for Type 303SS.

### **Waspaloy**

The Waspaloy material had a UTS of 1,392 MPa (202 ksi) and a YS of 1,024 MPa (148.6 ksi). The chemistry of Waspaloy is shown in Table 7. Hydrogen desorption curves are shown in Figures 13 through 17. Results were obtained under stresses of 0, 256 MPa (37.2 ksi), 512 MPa (74.3 ksi), 768 MPa (111.4 ksi), and 922 MPa (133.7 ksi), representing 0, 25, 50, 75, and 90 percent of the YS.

Results from the data analyses are presented in Table 8. As with the previous cases, there is no significant trend in values of the diffusion coefficients. Values of  $C_o$  and  $\bar{C}$  are generally higher for specimens under stress, although there is some scatter. Results for the percent uniformity show a much less pronounced trend with increasing stress than the two iron-based alloys previously discussed. Hence, the permeability of this alloy is much less affected by stress than are those for A286 CRES and 303SS. The curve relating the variation of percent uniformity with percent yield is shown in Figure 18, with all observed data points again being fitted with a second-degree polynomial.

The hydrogen trapping as a function of stress is shown in Table 9. The average percent trapped hydrogen is 20.6 percent.

### **IN100**

The IN100 material obtained from a powder metallurgy isothermal forging, heat treated at Sintech, Inc., had a UTS of 1,606 MPa (233 ksi) and a YS of 1,160 MPa (168.3 ksi). The chemistry of this material is shown in Table 10. Hydrogen desorption curves are shown in Figures 19 through 23. Results were obtained under stresses of 0, 290 MPa (42 ksi), 580 MPa (84 ksi), 870 MPa (126 ksi), and 1,044 MPa (151 ksi). These stress levels represent 0, 25, 50, 75, and 90 percent of the YS, respectively.

Results from the data analyses are presented in Table 11. There is again no significant trend in the values of the diffusion coefficients. The results are somewhat surprising, since it is obvious that IN100 shows no effects due to stress. The values of  $\bar{C}$  appear to actually decrease with increasing stress, although this is probably attributable mostly to scatter in the experimental results. The percent uniformity remains 100-percent nonuniform throughout, indicating no increase in permeability. This is to be compared with the results obtained for A286 CRES, Type 303SS, and Waspaloy. A286 CRES and Type 303SS, both iron-based alloys, show the most pronounced changes in permeability with stress, while Waspaloy, a nickel-based alloy, is only slightly affected.

Hydrogen trapping as a function of stress is shown in Table 12. The average percent trapped hydrogen is 21.5 percent, comparable to the value obtained for Waspaloy (20.6 percent). Thus, the value of 62.3 percent obtained for Type 303SS is far higher than the values obtained for the other three alloys.

## DISCUSSION AND CONCLUSIONS

The results all show no significant trends in values of the hydrogen diffusion coefficients, in agreement with the results of Bockris et al.<sup>2</sup> Distinct increases in the mean mobile hydrogen concentrations were observed at higher stress levels for Type 303SS, A286 CRES, and slightly in Waspaloy, but not observed for IN100, where there was no effect due to stress.

Since the values of the diffusion coefficients were nearly the same for all four metal alloys, the increased hydrogen penetration in type 303SS, A286 CRES, and Waspaloy on charging cannot be explained using standard diffusion theory along with the observed hydrogen diffusion coefficients, which were obtained in hydrogen desorption measurements. It is likely that the increased penetration is due to increased permeability. For a thin membrane, the permeability is given by

$$\text{Permeation} = \frac{DSP}{L} . \quad (1)$$

Here,  $D$  is the hydrogen diffusion coefficient,  $S$  is the solubility of hydrogen,  $P$  is the exterior hydrogen pressure, and  $L$  is the membrane thickness. Percent uniformities of the hydrogen distributions are accompanied by factors related to the solubility of hydrogen in the metals, namely the mean mobile hydrogen concentrations  $\bar{C}$ .

The difference between the permeability of hydrogen in iron-base alloys and that in the nickel-base alloys has not previously been observed. From this limited work, it is too early to make a generalization that all iron-base and nickel-base alloys are affected differently by tensile stress, the iron-base alloys being much more affected than the nickel-base alloys. However, the observations made in this work might be an indication that this could be the case.

# Type 303 Stainless Steel, No Stress, 25 °C

Figure 1. Hydrogen Desorption Curves for Type 303SS at Zero Stress.

# Type 303 Stainless Steel, 25% of Yield, 25 °C

Figure 2. Hydrogen Desorption Curves for Type 303SS at 25 Percent of Yield.

## Type 303 Stainless Steel, 50% of Yield, 25 °C

Figure 3. Hydrogen Desorption Curves for Type 303SS at 50 Percent of Yield.

# **Type 303 Stainless Steel, 75% of Yield, 25 °C**

Figure 4. Hydrogen Desorption Curves for Type 303SS at 75 Percent of Yield.

## Type 303 Stainless Steel, 90% of Yield, 25 °C

Figure 5. Hydrogen Desorption Curves for Type 303SS at 90 Percent of Yield.

## Type 303 Stainless Steel Percent Uniformity Versus Percent of Yield

Figure 6. Least-Squares Fit of a Second-Degree Polynomial to Percent Uniformity Versus Percent Yield for Type 303SS.

# A286 CRES, No Stress, 25 °C

Figure 7. Hydrogen Desorption Curves for A286 CRES at Zero Stress.

# A286 CRES, 25% of Yield, 25 °C

Figure 8. Hydrogen Desorption Curves for A286 CRES at 25 Percent of Yield.

# A286 CRES, 50% of Yield, 25 °C

Figure 9. Hydrogen Desorption Curves for A286 CRES at 50 Percent of Yield.

# A286 CRES, 75% of Yield, 25 °C

Figure 10. Hydrogen Desorption Curves for A286 CRES at 75 Percent of Yield.

# A286 CRES, 90% of Yield, 25 °C

Figure 11. Hydrogen Desorption Curves for A286 CRES at 90 Percent of Yield.

## A286 CRES

### Percent Uniformity Versus Percent of Yield

Figure 12. Least-Squares Fit of a Second-Degree Polynomial to Percent Uniformity Versus Percent Yield for A286 CRES.

# Waspaloy, No Stress, 25 °C

Figure 13. Hydrogen Desorption Curves for Waspaloy at Zero Stress.

# Waspaloy, 25% of Yield, 25 °C

Figure 14. Hydrogen Desorption Curves for Waspaloy at 25 Percent of Yield.

# Waspaloy, 50% of Yield, 25 °C

Figure 15. Hydrogen Desorption Curves for Waspaloy at 50 Percent of Yield.

## Waspaloy, 75% of Yield, 25 °C

Figure 16. Hydrogen Desorption Curves for Waspaloy at 75 Percent of Yield.

# Waspaloy, 90% of Yield, 25 °C

Figure 17. Hydrogen Desorption Curves for Waspaloy at 90 Percent of Yield.

## Waspaloy Percent Uniformity Versus Percent of Yield

Figure 18. Least-Squares Fit of a Second-Degree Polynomial to Percent Uniformity Versus Percent Yield of Waspaloy.

# IN100, No Stress, 25 °C

Figure 19. Hydrogen Desorption Curves for IN100 at Zero Stress.

## IN100, 25% of Yield, 25 °C

Figure 20. Hydrogen Desorption Curves for IN100 at 25 Percent of Yield.

# IN100, 50% of Yield, 25 °C

Figure 21. Hydrogen Desorption Curves for IN100 at 50 Percent of Yield.

# IN100, 75% of Yield, 25 °C

Figure 22. Hydrogen Desorption Curves for IN100 at 75 Percent of Yield.

# IN100, 90% of Yield, 25 °C

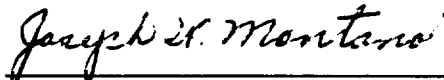

Figure 23. Hydrogen Desorption Curves for IN100 at 90 Percent of Yield.

APPROVAL

THE EFFECT OF TENSILE STRESS ON HYDROGEN  
DIFFUSION IN METAL ALLOYS

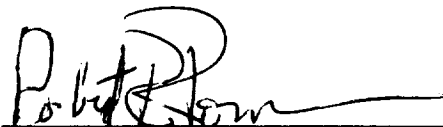

By M. D. Danford

The information in this report has been reviewed for technical content. Review of any information concerning Department of Defense or nuclear energy activities or programs has been made by the MSFC Security Classification Officer. This report, in its entirety, has been determined to be unclassified.
